```

`sub_1006e1bc` has no recorded callers; it is likely reached through the vector table or an indirect jump. It delegates to sub_1006b399 (1 callees).

13 Dynamic Analysis (Emulated)

Observed: the entry point was executed in a sandboxed, pure-software p-code interpreter. The target's own instructions ran without any native execution on the host, so this reflects the program's real behavior rather than its static form.

Derived: emulation from 0x1006b798 executed 67 instructions before stopping at 0x0; control left the mapped image on a return or external call.

14 Packing and Obfuscation

Inferred: the target is not packed (score 0; threshold 3).

No packing signals fired.

15 Methodology and Limitations

- Identified the format from file signatures and fingerprinted the file with MD5, SHA-1, and SHA-256.
- Parsed PE, ELF, and Mach-O headers, sections, imports, exports, symbols, and build metadata.
- Measured Shannon entropy for the file and every section.
- Extracted ASCII and UTF-16LE strings and classified network, path, registry, and command indicators.
- Classified imported APIs into capability categories and evaluated security mitigations from header fields.
- Disassembled x86/x86-64 with iced-x86 and every other supported architecture through an embedded SLEIGH engine, by recursive descent.
- Ranked functions by the capabilities and indicators they touch and listed the most relevant ones.

15.1 Limitations

- Analysis is static: the target is never executed, so run-time behavior is inferred, not observed.
- Imports show what a program can call, not what it does; dynamically resolved APIs are invisible to import analysis.
- Disassembly covers code reachable from the entry point, exports, and symbols; indirect-only code may be missed.
- A few architectures are parsed but not yet disassembled; for those, code analysis is omitted.
